Published With international search report.

(54) Title: RETRACTABLE I-V CATHETER PLACEMENT DEVICE

## (57) Abstract

An intravenous catheter placement device (1) having a hollow body (17) with a nose (3) on one end. A needle hub (41) fits within the nose (3), and contains a needle (13) embedded therein. A catheter (43) is free to slide along the needle (13), and substantially covers the shaft (39) of the needle (13). Winged beams (33, 33L) on the needle hub (41) include catches (35R, 35L), and release tabs (29R, 29L) that cooperate with slots (7R, 7L) in the nose (3) to retain the needle hub (41) in the nose (3). A magnifying transparent cavity (53) in the hub (41) provides for viewing blood flash in the cavity (53) to verify that the intravenous catheter (43) is inserted correctly. An energy storage device (15) in contact with the hub (41) releasably retains the hub (41) preventing premature projection of the hub (41) into the hollow body (17). Upon insertion of the catheter (43), the needle (13) into a patient, depressing the release tabs (29R, 29L) triggers the hub (41), blunts the needle (13) within the catheter (43), projects the hub (43), and needle (13) into the hollow body (17).

**RETRACTABLE I-V CATHETER PLACEMENT DEVICE****RELATED APPLICATIONS**

This application claims priority to U.S. Patent Applications No. 60/120,622 filed February 15, 1999, entitled  
5 "Retractable I-V Catheter Injection Device," No. 60/138,414  
filed June 8, 1999, entitled "Retractable I-V Catheter  
Injection Device," and Application filed February 11, 2000,  
entitled "Retractable I-V Catheter Placement Device,"  
application number not yet assigned, which are incorporated by  
10 reference herein.

**BACKGROUND OF THE INVENTION**

This invention relates generally to intravenous (I-V)  
catheter placement devices that reduce the likelihood of  
15 accidental needlestick injuries. In recent history, preventing  
the transmission of contagious diseases, particularly those  
brought about by the co-mingling of human body fluids, has been  
of great technological interest. One of the particular problems  
has been associated with the use and disposal of I-V catheter  
20 introducer needles by health care workers. There have been  
various devices developed for the destruction of the introducer  
needles or cannula used with I-V catheters. Additional devices  
have been developed for the capping or hooding of I-V catheter  
introducer needles, all of which attempt to minimize the  
25 likelihood of needlestick injuries to health care workers and  
others after the needles have been used. The accidental  
puncture or pricking of a finger, or any other part of the  
body, after the treatment of a patient with a contagious  
disease, particularly a deadly contagious disease, results in a  
30 high likelihood of transmission of blood borne pathogens and  
the associated disease.

### SUMMARY OF THE INVENTION

It is thus an feature of this invention to provide an I-V catheter placement system which minimizes the likelihood of accidental needlestick injuries.

5 It is a further feature of this invention to provide such an I-V catheter placement device which, after utilization with a patient, captures, encapsulates, and isolates the used needle so as to render such needle harmless.

10 It is a further and more particular feature of this invention to provide such an I-V catheter injection device that has two stages of needle isolation, which provides magnification of blood "flash-back" in the device, which provides blood flow restriction, and which is operable utilizing only one hand which remains always behind the tip of the needle during the  
15 operation of the device and its safety features.

It is a still further feature of the invention to provide a simple device which is manufacturable in high volumes.

20 These as well as other features are accomplished by an I-V catheter injection device having a hollow body or barrel, with a nose attached to one end of the body and closed at the opposite end. The nose is disposed to the interior of said hollow body through a passageway, integral to the nose.

One end of a hollow needle, which is embedded in a hollow and transparent needle hub, is controlled in the passageway  
25 within the nose by a shaft appendage of the needle hub, and is in contact with energy storage means such as a spring, placed into the passageway ahead of the needle hub shaft. The other end of the needle passes through the spring and the passageway, and protrudes through boot (which may be elastic or rigid) that  
30 is attached to the nose of the catheter injection system. Covering the exposed shaft of the needle, while leaving the point of the needle exposed, is a thin wall concentric sleeve, or catheter, which is free to slide completely along the distal end of the needle. The needle hub shaft, onto which the  
35 opposite, proximal end of the needle is attached, is fixed to a

transparent needle hub. The needle hub has two symmetrical winged beams, which are cantilevered from the back of the needle hub in the direction of the needle hub shaft and project at an angle away from the needle hub shaft and needle hub.

5       The geometry of the distal end of each winged beam is defined with angled catches for fixing the needle hub, with the spring in contact with it, into retainer slots in the sidewall of the nose. On the adjacent side of each catch is a release contact point for operationally releasing the needle hub from  
10       retainer slots during retraction of the needle and needle hub into the body of the device during use of the device. In an assembled state, the needle hub is held by one of the catches on the winged beams in position in the nose against the spring and ready for use. The opposite catch floats in its nose slot,  
15       which is slightly longer than the first nose slot, until actuation of the retraction cycle.

Use of the I-V catheter placement device is accomplished by holding the device at the finger grips in one hand with the orientation message "USE THIS SIDE UP," inscribed on the body  
20       of the device, visible to the clinician and with the needle pointing away from the clinician. The injection site of the patient is held with the other hand, such that the second hand is behind the needle at all times and is thus shielded from possible accidental needlestick. The introducer needle, with  
25       the catheter, is then injected part way into the patient's vein at the desired location, such that just the tip of the needle and catheter have been inserted. The clinician then receives visual verification of proper veinal placement of the needle and catheter by observing the appearance of blood "flash-back"  
30       in the inner cavity of the needle hub (which is magnified).

When proper entrance of the needle and the catheter tip into the patient's vein is confirmed, two release tabs on the sides of the body of the device are simultaneously depressed and released, causing the needle tip to retract just inside the  
35       tip of the catheter. As the needle and needle hub retract,

visible indication of such retraction is provided to the clinician, whereby the needle hub is stopped at a fixed reference line on the body labeled as "1". In addition, audible indication of such retraction is provided by a "clicking" sound which is audible when the release tabs are depressed, and again when they are released. With the needlepoint effectively blunted inside the tip of the catheter, complete insertion of the catheter is then accomplished by the user without risk of the needle tip piercing the backside of the vein and thus "blowing the vein."

Once the catheter is properly inserted into the patient's vein, the two release tabs on the sides of the body are again simultaneously depressed and released. This action releases the remaining needle hub catch from its slot in the nose, and the needle hub with the needle attached thereto, is projected by stored energy in the spring (or other energy storage means) into and retained within the body of the device. Visible verification of such needle retraction is provided to the clinician by him or her observing that the needle hub is positioned at a second fixed reference line at the back of the body of the device labeled as "2." In addition, audible indication of such retraction is provided by a "clicking" sound which is audible when the release tabs are depressed. As the needle tip passes the boot at the nose of the device, the hole in the boot through which the needle has passed closes, and blood flow from the catheter into the body of the device is restricted.

External blood flow from the device is further restricted by the sealing action between the boot and the internal wall of the catheter head. With the needle safely contained within the body of the device, the clinician applies digital pressure at the entry point of the catheter into the patient's body to block blood flow from the catheter, removes the body of the device (which acts as a plug in the catheter head), and inserts the I-V line into the catheter head. Digital pressure is then

removed, completing the process. An alternative embodiment of this invention provides for sequential depression of the individual release tabs to actuate needle retraction.

An alternative embodiment of this invention provides a second method of automatically plugging the nose of the device for flow restriction and added needle security.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a longitudinal cross-sectional view of the I-V catheter placement device of this invention in its operable state with the needle, or distal end, on the left.

Figure 2 is a longitudinal cross-sectional view of the I-V catheter placement device shown in Figure 1 in its post operational state.

Figure 3 is an isolated top view of the nose of the catheter placement device shown in Figure 1.

Figure 4 is a proximal end view of the nose shown in Figure 3.

Figure 5 is an elevational side view of the spring of this invention.

Figure 6 is a top view of the barrel of the device shown in Figure 1.

Figure 7 is a distal end view of the barrel shown in Figure 6.

Figure 8 is a side view of the needle hub of the device shown in Figure 1.

Figure 9 is proximal end view of the needle hub shown in Figure 8 well illustrating the magnification surfaces of the needle hub.

Figure 10 is an isolated longitudinal section view of the catheter of the device shown in Figure 1.

Figure 11 is an isolated sectional view of the membrane of the device shown in Figure 1.

Figure 12 is an isolated sectional view of a needle guard for use with the device shown in Figure 1.

Figure 13 is a proximal end view of the boot of the device shown in Figure 1.

Figure 14 is a sectional view along line 14-14 of Figure 13.

5        Figures 15-20 illustrate the assembly of the device shown in Figure 1.

Figures 21-27 illustrate the operation of the device shown in Figure 1.

10       Figures 28-36 illustrate modified parts for an alternative embodiment of the device shown in Figure 1.

Figures 37, 38 and 39 illustrate assembly of the alternative embodiment from the parts illustrated in Figures 28-36.

15       Figures 40, 41, and 42 are partial, longitudinal sectional views illustrating the operation of the alternative embodiment of the catheter placement device of this invention shown in Figures 28-39.

#### DETAILED DESCRIPTION

20       This invention provides an I-V catheter placement device operable with one hand and having a two-stage needle retraction mechanism using one set of release tabs. The first stage of retraction effectively blunts the needle tip and allows insertion of the full length of the catheter without risk to  
25       the patient, while the second stage of retraction fully retracts the needle hub, with its contaminated introducer needle attached, harmlessly into the body of the catheter placement device where it is captured and encapsulated, thus protecting the clinician from an accidental needlestick injury.

30       Once encapsulated inside the body of the catheter placement device, there is no risk of accidentally pricking or poking human tissue, thus minimizing the likelihood of transfer of blood borne pathogens which may be carried by fluids contained on the surface of or within such needle. Other

advantages and features will become apparent from the following description and reference to the Figures.

Figures 1 and 2 illustrate the catheter placement device 1 of this invention with the needle 13 and catheter 43 in its normal pre-injection position. Figure 2, however, shows the final position of the needle 13 after operation of the retraction cycle so that the needle hub 41 (with needle 13 attached) is held in hollow catheter body 17 and rendered harmless after the placement of the catheter 43 has taken place. The I-V catheter placement device 1 has relatively few components.

Referring to Figure 1, I-V catheter placement device 1 has a hollow barrel or body 17 with a nose 3 attached to one end. Barrel 17 is closed at the opposite end. A passageway 9 through nose 3 communicates with the interior of the hollow barrel 17. A proximal end of hollow needle 13 is fixed in a through hole 14 of needle hub shaft 39, which is in communication with a magnified blood "flash-back" verification cavity 53 in needle hub 41. Membrane 31 is positioned in the verification cavity 53 remote from needle 13 to allow airflow through membrane 31 but to prevent flow of blood into hollow barrel 17 as the catheter is inserted into a patient's vein.

Needle hub 41 is controlled in the passageway 9 within the nose 3 by needle hub shaft 39, and is in contact with spring 15, which is compressed into the passageway 9 ahead of needle hub shaft 39. The distal end of the needle 13 passes through spring 15, passageway 9, and nose boot 25 and protrudes from the nose end of the catheter injection system 1. Covering the exposed shaft of the needle 13, while leaving the point of the needle 13 exposed, is a thin wall concentric sleeve, or catheter 43, which is free to slide completely along the distal end of needle 13. Catheter 43 is fixed to nose 3 at catheter head 45 by light friction between catheter head 45 and nose boot 25 which provides a liquid tight seal between the catheter

head 45 and nose boot 25 and also makes them easily separable during use.

Needle hub shaft 39, into which is fixed the proximal end of needle 13 in a through hole 14 running the length of shaft 39, is an appendage of needle hub 41. Needle hub 41 has winged beams 33R and 33L which are cantilevered from the back of the needle hub 41 in the direction of the needle hub shaft 39 and project at an angle away from needle hub shaft 39. The geometry of the distal end of winged beams 33R and 33L is defined with an angled catch 35R for coupling the needle hub 41, with spring 15 in contact therewith, into retainer slot 7R in the side wall of nose 3. On the adjacent side of catch 35R is a release contact point 37R for operationally releasing needle hub 41 from retainer slot 7R through the application of force during retraction of the needle 13 into the body 17 during use. In its pre-activated retraction state, spring 15 urges needle hub 14 away from nose 3. However, needle hub 41 is held by angled catch 35R on winged beam 33R in its position in passageway 9.

Use of I-V catheter placement device 1 is accomplished by holding the catheter placement device 1 at its symmetrical finger grips 27 in one hand such that orientation message 63 "USE THIS SIDE UP" is readable by the clinician, with needle 13 pointed away from the clinician. The placement site of the patient is held with the other hand, such that the second hand is behind the needle at all times and is intrinsically protected from possible needlestick by the patient's body. The tip or point 59 of needle 13, with the catheter 43, is just placed into the patient at the desired location. Verification of correct location of the catheter 43 is obtained by clinician observation of blood flash-back into magnified transparent verification cavity 53 in needle hub 41. Once proper location is confirmed, release tabs 29R and 29L are simultaneously depressed two times a) effectively to blunt the needle tip, and b) to retract needle 13 into the body of catheter 17.

As may be seen in Figure 2 and Figure 1, actuation of the catheter placement device 1 retraction cycle occurs when release tabs 29R and 29L, just in front of finger grips 27 of the catheter placement device 1, are simultaneously depressed.

5 When this occurs, force is applied by contact pads 19R and 19L on the interior surfaces of release tabs 29R and 29L to release contact points 37R and 37L on the winged beams 33R and 33L of the needle hub 41. As force is applied, inward movement of catches 35R and 35L in their respective retaining slots 7R and  
10 7L occurs, and catches 35R and 35L, holding the needle hub 41 into its cocked position, are subsequently released in two sequential depressions of release tabs 29R and 29L. As catch 35L releases from retainer slots 7L, there is nothing to restrain needle hub 41, and needle hub 41 is triggered,  
15 allowing energy stored in spring 15 to be released, projecting needle hub 41 with its embedded needle 13 towards the closed end of barrel 17. Once needle hub 41 is released, it is guided by channels 23 on an interior of the barrel 17 towards the closed end of barrel 17. Needle hub 41 is prevented from  
20 escaping from the interior of the barrel 17 by residual force from spring 15.

Figures 3 through 10 more particularly illustrate the components of I-V catheter placement device 1.

Figure 3 is an isolated top view of nose 3 showing  
25 passageway 9. Retainer slots 7R and 7L which lock the needle hub 41 into its operational positions are also shown. Longitudinal grooves or channels 5 guide the needle hub 41 in the nose 3 during the retraction cycle, and stop 67 helps capture catch 35L during the first stage of needle retraction  
30 of needle hub 41.

Figure 4 is proximal end view illustrating nose 3 of this invention and showing the channels 5 and tabs 11. Tabs 11 are used to attached the nose 3 to body 17.

Figure 5 is an elevational view of the spring 15.

Figure 6 is a top view of body 17. Release tabs 29R and 29L project from symmetrical finger grips 27, and slots 21 on both the top and bottom sides of the body 17 receive tabs 11 when attaching the nose 3. Contact pads 19R and 19L on the interior surfaces of the release tabs 29R and 29L cooperate with release catches on the needle hub. Also illustrated in this view are channels 23 which guide the needle hub 41 in the body 17 during retraction of needle hub 41, and the orientation message "USE THIS SIDE UP," with two reference lines labeled as "1" and "2" to show the positions of the needle hub during both stages of needle retraction.

Figure 7 is a distal end view of body 17, illustrating release tabs 29R and 29L, channels 23, and contact pads 19R and 19L, and air release hole 47 in the proximal end of barrel 17.

Figure 8 is a side view of needle hub 41 illustrating the space 31' for membrane 31, transparent verification cavity 53, winged beams 33, catches 35, release contacts 37 and the needle hub shaft 39 projecting between winged beams 33.

Figure 9 is a proximal end view of needle hub 41 showing magnification surfaces 73 of verification cavity 53 that act as lenses to make the presence of blood in cavity 53 easier to determine.

Figure 10 is a longitudinal sectional view of the catheter 43 and catheter head 45.

Figure 11 is an isolated sectional view of the membrane 31.

Figure 12 is an isolated longitudinal sectional view of needle guard 51 illustrating guard-locking ring 49.

Figure 13 is a proximal end view of boot 25, and Figure 14 is a sectional view along line 14-14 of boot 25.

Assembly in several steps is required to produce the I-V catheter placement device 1. Figures 15 through 20 illustrate these steps so as to result in a finished product. With reference to Figure 15, the first assembly step is accomplished by inserting needle 13, with its bevel 57 up, into the needle

hub shaft 39 of needle hub 41. As is illustrated, this gives needle hub 41 a specific orientation, with its elemental parts having the designations shown. The membrane 31, which may be a hydrophilic medium, is inserted into the hub 41 in the properly sized space 31' provided to receive it.

In the next step of the assembly process, boot 25 is inserted onto nose 3 as illustrated in Figure 16. Orientation of nose 3 is determined by reference to slots 7R and 7L because slot 7L is slightly longer than slot 7R. The needle 13 and hub 41 subassembly shown in Figure 15 are next inserted into the proximal end of nose 3, as shown in Figure 17, by first guiding spring 15 onto needle 13. Orientation of the hub 41 and nose 3 is accomplished by insuring that catch 35R is mated with slot 7R. Once properly oriented, needle 13 is then guided through passageway 9 and projected out of nose 3, penetrating boot 25.

As winged beams 33R and 33L approach nose 3, they are aligned with channel 5, flexed inward to create a spring affect along the beam, to fit the beams into channels 5 on either side of nose 3. With the winged beam 33R and 33L guided in channels 5, the needle hub 41 is forced into the nose 3 as shown in Figure 17, until needle catch 35R pops into slots 7R. Catch 35R remains in slots 7R due to spring force of the compressed winged beam 33R and the angle of catch 35R. This process locks needle hub 41 into nose 3. Needle catch 35L floats in slot 7L.

Figure 18 shows a proximal end view of needle hub 41 fixed into nose 3.

The next step of the assembly process is attachment of body 17 to the sub-assembly of Figure 17. As shown in Figure 19, body 17 is aligned with the subassembly of Figure 17 such that bevel 57 on needle 13 and orientation message 63, "USE THIS SIDE UP" on the top of body 17 face in the same direction.

Once orientation is accomplished, body 17 is passed over the proximal end of nose 3, and attachment to nose 3 is accomplished by aligning and forcing slots 21 on body 17 (shown in Figure 6) over tabs 11 on the nose 3 (shown in Figures 3 and

4) until they snap into position. The barrel 17 and nose 3 are mechanically keyed with side 69L being slightly wider than side 69R (shown in Figure 4), so that they will only go together in the correct orientation.

5       As is illustrated in Figure 20, assembly of the I-V catheter placement device 1 is completed by placing catheter 43 over needle 13 and sliding catheter head 45 onto boot 25 at nose 3. The catheter head 45 is held in place by light friction between the catheter head 45 and boot 25. Once the  
10 catheter 43 is in place, needle guard 51 is locked onto nose 3 by guard-locking ring 49, completing the assembly process.

As will be apparent to those of ordinary skill in the art, there are sequences of assembly other than those described that can be used to produce the completed assembly as shown in  
15 Figure 20, producing the same I-V catheter placement device 1 ready for operation.

The sequence of operation will now be described with regard to Figures 21 through 27. As can be seen in Figure 21, use of I-V catheter placement device 1 is accomplished by  
20 holding the catheter placement device 1 at its symmetrical finger grips 27 in one hand such that the hand is always behind the needle tip and orientation message 63, "USE THIS SIDE UP," is readable by the clinician, with needle 13 pointed away from the clinician. The placement site of the patient is held with  
25 the other hand behind the needle, such that the second hand is protected from possible needlestick injury. The point 59 of needle 13, with the catheter 43 concentric therewith, is inserted into the patient's vein 55 at the desired location. Verification of correct location of the catheter 43 is obtained  
30 by observation of blood "flash-back" into magnified, transparent verification cavity 53 at the top of body 17. Once proper location is confirmed, release tabs 29R and 29L, located just in front of finger grips 27, are simultaneously depressed.

As release tabs 29R and 29L are simultaneously depressed,  
35 contact pads 19R and 19L move toward their respective needle

catches 35R and 35L, and an audible "click" sound is produced.

Because of the design geometry, contact pad 19L moves into slot 7L, behind catch 35L, before pad 19R comes into contact with push point 37R. Continued simultaneously movement of the two release tabs causes catch 35L to become "trapped" in slot 7L between stop 67 and pad 19L, before pad 19R forces catch 35R out of the back of slot 7R. As pad 19R forces catch 35R out of slot 7R, needle hub 41, with needle 13 attached therewith, becomes unrestrained and begins to retract under force from spring 15 into the hollow of body 17. Retraction continues until catch 35L contacts pad 19L, and retraction is stopped as shown in Figure 21. In this state, push point 37R is captured in channel 5 within nose 3, where it can no longer affect retraction of needle hub 41 into body 21.

As is shown in Figure 22, exertion of pressure on release tabs 29R and 29L is discontinued (although the device continues to be held by the clinician by such release tabs) by the clinician and such release tabs are allowed to return to their initial, rest positions, at which time another audible "click" sound is produced. As release tab 29L returns to its rest position, pad 19L releases catch 35L. At the moment catch 35L is released by pad 19L, positive feedback between the two parts is used, increasing the lateral distance between the two parts, to obtain an unobstructed, smooth release of needle hub 41. Once released, needle hub 41, with needle 13 attached therewith, again becomes unrestrained, allowing further retraction into the hollow of body 17 under the force of spring 15.

Retraction continues until catch 35L comes into contact with the back of slot 7L and all movement stops. In this state, the first stage of retraction is completed, needle tip 59 is withdrawn within catheter 43 as shown in Figure 23, and needle hub 41 is at the fixed reference line "1" 61. Full insertion of the catheter 43 may now be completed.

With needle tip 59 effectively blunted by catheter 43, full insertion of the catheter into the patient's vein 55, without risk of piercing the backside 71 of vein 55 ("blowing the vein") is accomplished without risk to the patient, as shown in Figure 24.

With the catheter fully inserted into the patient's vein 55 as shown in Figure 25, second stage retraction is accomplished by simultaneously depressing release tabs 29R and 29L a second time, which produces an audible "click" sound. When this is done, no further reaction is obtained by release tab 29R, other than to balance the force required to depress the opposite release tab 29L, which adds stability for one-handed operation of the device. However, as release tab 29L moves inward, pad 19L contacts push point 37L. With continued force and movement, catch 37L is dislodged from slot 7L. When this occurs, needle hub 41, with needle 13 attached, again becomes unrestrained and is projected along channels 5 and 23, in nose 3 and body 17 respectively, into hollow 17 by the force of spring 15 as shown in Figure 25. Needle hub 41 is then held in its retracted position at reference line "2" 65 by residual force from spring 15. As needle tip 59 passes through boot 25, the hole left in elastic boot 25 closes, preventing blood flow from the catheter into the hollow of body 17. External blood flow from the catheter at nose 3 is prevented by boot 25 being in radial contact with the internal surface of catheter head 45. With all blood flow restricted, catheter body 17 acts as a "plug" in the end of catheter head 45, until it is removed and an I-V line set is plugged into the catheter. Exertion of pressure on release tabs 29R and 29L by the clinician is discontinued (although the device continues to be held by the clinician by such release tabs), and such release tabs are allowed to return to their initial, rest positions.

Completion of the catheter placement process is depicted in Figures 26 and 27. First, digital pressure 75 is applied at vein 55, where the catheter is inserted into the body. This

stops blood flow from the catheter when catheter body 17 is removed. With blood flow blocked, catheter body 17 is removed and safely set aside for later disposal as shown in Figure 27. Next, I-V line set 77 is inserted into catheter head 45.

5 Digital pressure 75 is then removed, completing the process.

As can be understood by reference to Figures 21 through 27, an alternative method of needle retraction can be practiced by depressing release tabs 29R and 29L in a sequential fashion.

For this method, release tab 29R is first depressed and then  
10 released. When release tab 29R is depressed, catch 35R is dislodged from the back of slot 7R. When this occurs, needle hub 41, with needle 13 attached therewith, becomes unrestrained, since catch 35L is only floating in its slot 7L.

Retraction continues until catch 35L is stopped at the back of  
15 slot 7L, as shown in Figures 22 and 24, effectively blunting needle point 59 within catheter 43. Needle hub 41 is at reference line "1" 61.

For the second stage of needle retraction, release tab 29L is depressed and released, dislodging catch 35L from the back  
20 of slot 7L. As catch 35L is dislodged from slot 7L, needle hub 41, and the attached needle 13 are projected into hollow body 17 as previously described. Completion of the cycle occurs as previously described.

A second embodiment of this invention, catheter 101, is  
25 shown in Figure 39. Catheter placement device 101 has a modified nose, which provides for a) an alternative flow restriction mechanism after the needle is retracted, and b) secondary locking of the retracted needle within the body of the catheter. Figures 28 through 42 depict the second  
30 embodiment. Figures 28 through 36 depict the modified parts for catheter 101. Figures 28, 29, and 30 illustrate nose 103 modified with through hole 195 transverse to the longitudinal axis of catheter 101. Figure 31 is a side view of top plug 196, Figure 32 is a side view of shuttle spring 197, Figure 33  
35 is a side view of shuttle 198, and Figure 34 presents a side

view of a bottom plug 199. Figure 35 is an end view of nose seal 125, while Figure 36 is a sectional view of nose seal 125 along line 36-36.

Figures 37-39 depict assembly of catheter 101. Needle hub 141 and needle 113 are assembled into nose 103 in the same manner as catheter 1. Nose seal 125 is inserted onto nose 103, and results in the subassembly shown in Figure 37. With needle hub 141 and needle 113 fixed in nose 103 as shown in Figure 38, cylindrical plug 199 is inserted into one end of through hole 195. In the other end of through hole 195, cylindrical shuttle 198 with tapers at each end, as illustrated in Figure 33, is first inserted, followed by shuttle 198. The assembly process is completed by compressing shuttle spring 197 and inserting plug 196 into through hole 195 in nose 103 as shown in Figures 38 and 39. The assembly process is completed by fixing body 117 to nose 103 as in the case of catheter 1, producing catheter 101 shown in Figure 39. As will be appreciated by reference to Figure 40, compressed spring 197 is restrained within nose 103 by retaining plug 196 on one end and shuttle 198 at the opposite end, and applies force to one side of shuttle 198, as shown in Figures 38 and 39. The side of shuttle 198 opposite spring 197 is restrained in one half of through hole 195 by the shaft of needle 113 in passageway 109 of nose 103 as illustrated in Figures 39 and 40.

Utilization of catheter 101 is the same catheter 1. After the catheter is properly placed into the patient and release tabs 129 have been actuated to project needle 113 into the body 117 of catheter 101 as shown in Figure 40, the point 159 of needle 113 passes shuttle 198. Once point 159 of needle 113 passes shuttle 198, shuttle 198 becomes unrestrained and is projected into passageway 109 of nose 103 by force from shuttle spring 197, thus blocking passageway 109 as illustrated in Figure 41. The final operation is illustrated in Figure 43, where the catheter 101 is removed from the catheter head 145

and an I-V line set 177 is inserted into catheter head 145 as described for catheter 1.

The alternate embodiments of this invention provide a novel I-V catheter placement apparatus that is operable by a single hand and that, upon completion of catheter injection, captures and encapsulates the needle and renders it harmless within the hollow of the body of the device. Alternative configurations, including one utilizing only one release tab, will become apparent to those skilled in the art from a reading of the foregoing description, which is exemplary in nature. All such modification and variations are embraced within the scope of this invention and the following claims.

**Claims:**

- 1 1. A system for retracting an introducer needle of a catheter  
2 placement device, comprising:  
3 a hollow body having a closed end, a nose attached to an  
4 open end and release tabs;  
5 a needle hub having the introducer needle embedded  
6 therein, the needle hub releasably attached to the nose;  
7 an energy storage device in contact with the needle hub;  
8 and  
9 a catheter substantially covering the introducer needle  
10 and releasably affixed to the nose.
- 1 2. The system of claim 1, further comprising a catheter head  
2 affixed to the catheter.
- 1 3. The system of claim 2, further comprising a nose boot  
2 attached to and covering an end of the nose and penetrable by  
3 the introducer needle, the nose boot cooperating with the  
4 catheter head to provide a liquid tight seal therebetween.
- 1 4. The system of claim 1, wherein the needle hub further  
2 comprises two winged beams having ends, cantilevered from a  
3 back portion of the needle hub and projecting at an angle away  
4 from the needle hub, the ends of the winged beams defining  
5 angled catches.
- 1 5. The system of claim 4, wherein the release tabs are  
2 adjacent to the angled catches.
- 1 6. The system of claim 4, further comprising retainer slots  
2 in sidewalls of the nose whereby the angled catches of the  
3 winged beams hold the needle hub in the retainer slots.

1 7. The system of claim 2, further comprising a seal for  
2 providing a liquid impervious seal between the nose and a  
3 catheter head.

1 8. The system of claim 1, wherein the energy storage device  
2 surrounds a portion of the needle hub.

1 9. The system of claim 1, further comprising a needle guard  
2 removably attached to and covering the introducer needle, nose,  
3 catheter, release tabs and a portion of the hollow body.

1 10. The system of claim 1, wherein the nose is generally  
2 elliptical.

1 11. The system of claim 1, wherein the needle hub is hollow  
2 and includes a magnified transparent cavity.

1 12. The system of claim 1, wherein upon an initial depression  
2 and release of the release tabs, a tip of the introducer needle  
3 partially retracts within an end of the catheter, and upon  
4 subsequent depression of the release tabs, the energy storage  
5 device triggers and projects the needle hub and attached  
6 introducer needle into an interior of the hollow body.

1 13. The system of claim 1, further comprising a membrane  
2 affixed to a distal end of the needle hub adapted to allow air  
3 flow through the membrane and prevent liquid flow into the  
4 hollow body as the catheter is inserted into a human body.

1 14. The system of claim 1, wherein the hollow body includes  
2 indicia on a portion of the hollow body.

1 15. A needle retraction system for an intravenous catheter  
2 placement device, comprising:

3 a hollow body having a closed end and a nose within the  
4 hollow body attached to the other end;

5 a needle hub having integral winged beams and a needle  
6 embedded therein, the needle hub coupled to the nose;

7 retainer slots on the nose holding catches forming ends of  
8 winged beams, the catches on the winged beams angled to prevent  
9 the winged beams from prematurely disengaging from the retainer  
10 slots;

11 an energy storage device in contact with the needle hub;  
12 and

13 a catheter substantially covering the needle and  
14 releasably affixed to the nose, whereby upon simultaneously  
15 depressing and then releasing the release tabs, the needle hub  
16 is triggered, projecting the needle hub and attached needle  
17 into an interior of the hollow body and retaining the needle  
18 hub and attached needle within the hollow body.

1 16. The system of claim 15, further comprising a catheter head  
2 affixed to the catheter.

1 17. The system of claim 16, further comprising a nose boot  
2 attached to and covering an end of the nose and penetrable by  
3 the needle, the nose boot cooperating with the catheter head to  
4 provide a liquid tight seal therebetween.

1 18. The system of claim 15, further comprising a needle guard  
2 removably attached to and covering the needle, nose, release  
3 tabs, catheter and a portion of the hollow body.

1 19. The system of claim 15, wherein the nose is generally  
2 elliptical.

1 20. The system of claim 15, further comprising a membrane  
2 affixed to a distal end of the needle hub adapted to allow air

3 flow through the membrane and disallow liquid flow into the  
4 hollow body as the catheter is inserted into a human body.

1 21. A retractable intravenous catheter placement device,  
2 comprising:

3 a) a needle hub including:

4 i) winged beams and a shaft disposed therein;

5 ii) release points at ends of the winged beams;

6 iii) angled catches attached to each of the release  
7 points;

8 iv) a membrane attached to an end of the needle hub;

9 v) a cavity disposed within the needle hub; and

10 vi) a needle inserted into the shaft where a distal  
11 portion of the needle protrudes outwardly from the needle hub  
12 shaft;

13 b) a nose having a passageway therein, retainer slots  
14 cooperating with and locking in place the needle hub and a  
15 channel

16 along an interior wall of the nose;

17 c) a body having a closed end and an opposite end  
18 coupled to the nose, the body including finger grips on an  
19 external sides of the body and channels along the interior  
20 walls of the body;

21 d) a spring contacting the needle hub;

22 e) a catheter having a catheter head removably affixed  
23 to the nose and substantially covering the needle; and

24 f) a needle guard removably attached to and covering the  
25 needle, the catheter, release tabs, nose and a portion of the  
26 body.

1 22. A needle retraction system for an intravenous catheter  
2 placement device, comprising:

3 a hollow body having a closed end and a nose within the  
4 hollow body attached to the other end;

5 a shuttle positioned in a passageway of the nose;

6 a spring contacting the shuttle positioned in the  
7 passageway of the nose;

8 a needle hub having winged beams and catches on ends of  
9 the winged beams, the catches on the winged beams angled to  
10 prevent the winged beams from prematurely disengaging from  
11 retainer slots in the nose;

12 an energy storage device in contact with the needle hub;  
13 and

14 a catheter substantially covering the needle and  
15 releasably affixed to the nose, whereby upon depressing and  
16 releasing the release tabs projecting the needle past the  
17 shuttle, the shuttle becomes unrestrained and is projected into  
18 the passageway of the nose by the energy storage device,  
19 blocking the passageway, thereby restricting blood flow back  
20 into the hollow body and retaining the needle hub and attached  
21 needle within the hollow body.

1 23. A method for retracting an introducer needle of an  
2 intravenous catheter placement device, comprising:

3 inserting a tip of the introducer needle and an  
4 intravenous catheter into a human body;

5 simultaneously depressing and releasing release tabs of a  
6 hollow body of the an intravenous catheter placement device,  
7 thereby retracting the tip of the introducer needle inside an  
8 end of the intravenous catheter;

9 inserting the intravenous catheter further into the human  
10 body;

11 simultaneously depressing the release tabs thereby  
12 triggering an energy storage device in contact with a needle  
13 hub; and

14 projecting the needle hub and needle into the hollow body  
15 and retaining the needle hub and needle in the hollow body.

1 24. A method for retracting an introducer needle of an  
2 intravenous catheter placement device into a hollow body,  
3 comprising:

4 inserting a tip of the introducer needle with a catheter  
5 into a patient; and

6 simultaneously depressing release tabs affixed to the  
7 hollow body at least once to blunt the tip of the introducer  
8 needle into the catheter and to retract the introducer needle  
9 into the hollow body.

1 25. The method of claim 24, further comprising:

2 orienting the hollow body such that a message on the  
3 hollow body is readable by a clinician.

1 26. The method of claim 25, further comprising:

2 verifying that the catheter is inserted into the correct  
3 location by observing blood flash-back into a magnified  
4 transparent verification cavity in a needle hub.

1 27. The method of claim 24, further comprising:

2 confirming retraction of the introducer needle by  
3 observation of an audible clicking sound when the release tabs  
4 are depressed; and

5 securing the introducer needle in the hollow body by force  
6 of an energy storage device.

1 28. The method of claim 24, further comprising:

2 eliminating blood flow from the catheter into the hollow  
3 body utilizing a boot cooperating with an interior surface of a  
4 catheter head such that blood flow is restricted from flowing  
5 back into the hollow body.

1 29. The method of claim 24, further comprising:

2 eliminating blood flow from the catheter into the hollow  
3 body utilizing a shuttle and an energy storage device

4 positioned in a passageway of a nose that couples to the hollow  
5 body such that when the introducer needle passes the shuttle,  
6 the shuttle becomes unrestrained and is projected into the  
7 passageway by the energy storage device and blocks the  
8 passageway, thereby restricting blood flow back into the hollow  
9 body.

1 30. The method of claim 24, further comprising:

2 eliminating blood flow from the catheter into the hollow  
3 body utilizing a shuttle and an energy storage device  
4 positioned in a passageway of a nose that couples to the hollow  
5 body.

1 31. A method for retracting a needle affixed in a needle hub  
2 in a hollow body of an intravenous catheter placement device,  
3 comprising:

4 depressing release tabs having contact pads integral to  
5 the hollow body such that the contact pads apply force to  
6 winged beams of the needle hub having catches at their ends  
7 held by retainer slots in the hollow body;

8 releasing catches of the needle hub from the retainer  
9 slots and triggering the needle hub by releasing energy stored  
10 in an energy storage device;

11 projecting the needle hub and needle towards a closed end  
12 of the hollow body; and

13 securing the needle hub and needle in an interior of the  
14 hollow body with residual force from the energy storage device.

1 32. A system for retracting a needle of a catheter placement  
2 device, comprising:

3 a hollow body having a closed end, a nose attached to an  
4 open end and release tabs;

5 a needle hub having the needle embedded therein, the  
6 needle hub releasably attached to the nose;

7 an energy storage device in contact with the needle hub;

8 a catheter having a catheter head substantially covering  
9 the needle and releasably affixed to the nose; and

10 a nose boot attached to and covering an end of the nose  
11 and penetrable by the needle, the nose boot cooperating with  
12 the catheter head to provide a liquid tight seal therebetween.

1 33. A system for retracting a needle of a catheter placement  
2 device, comprising:

3 a hollow body having a closed end, a nose attached to an  
4 open end and release tabs;

5 a needle hub having a needle embedded therein, the needle  
6 hub releasably attached to the nose;

7 an energy storage device in contact with the needle hub;

8 a catheter substantially covering the needle and  
9 releasably affixed to the nose;

10 a catheter head affixed to the catheter;

11 a magnified transparent verification cavity in the needle  
12 hub for verifying that the catheter is inserted into the  
13 correct location by observing blood flash-back; and

14 a nose boot attached to and covering an end of the nose  
15 and penetrable by the needle, the nose boot cooperating with  
16 the catheter head to provide a liquid tight seal therebetween,  
17 wherein upon depressing the release tabs, a tip of the needle  
18 blunts into the catheter and upon a subsequent depression of  
19 the release tabs, the needle retracts into the hollow body.

1 34. A method for retracting an introducer needle of an  
2 intravenous catheter placement device into a hollow body,  
3 comprising:

4 inserting a tip of the needle with a catheter into a  
5 patient;

6 blunting the tip of the needle into the catheter by  
7 depressing release tabs affixed to the hollow body; and

8 depressing the release tabs to retract the needle into the  
9 hollow body.

1 35. A process for placing an intravenous catheter into a human  
2 body, comprising:

3 inserting an introducer needle with a catheter  
4 substantially covering the introducer needle into a human body;  
5 partially retracting the introducer needle inside an end  
6 of the catheter to blunt a tip of the introducer needle; and  
7 fully inserting the catheter into the human body.

1 36. A process for placing an intravenous catheter into a  
2 human body, comprising;

3 inserting an introducer needle with a catheter  
4 substantially covering the needle into a human body;  
5 retracting the introducer needle inside a hollow body of  
6 the catheter placement device; and  
7 restricting blood flow into the catheter during and after  
8 introducer needle retraction utilizing a boot coupled to the  
9 catheter placement device and adapted to perform as a plug in  
10 the catheter.

1 37. A system for retracting an introducer needle of a catheter  
2 placement device, comprising:

3 a hollow body having a closed end, a nose attached to an  
4 open end and a release tab;  
5 a needle hub having the needle embedded therein, the  
6 needle hub releasably attached to the nose;  
7 an energy storage device in contact with the needle hub;  
8 and  
9 a catheter substantially covering the needle and  
10 releasably affixed to the nose.

1 38. The system of claim 37, wherein upon depressing the  
2 release tab at least once, the needle retracts into the hollow  
3 body.
